The Institute for Defense Analyses is a nonprofit corporation that operates three Federally Funded Research and Development Centers. Its mission is to answer the most challenging U.S. security and science policy questions with objective analysis, leveraging extraordinary scientific, technical, and analytic expertise.

About This Publication

This work was conducted by the Institute for Defense Analyses (IDA) under contract HQ0034-19-D-0001, Task BD-09-229990, "TestSci App," for the Office of the Director, Operational Test and Evaluation. The views, opinions, and findings should not be construed as representing the official position of either the Department of Defense or the sponsoring organization.

Acknowledgments

The IDA Technical Review Committee was chaired by Dr. V. Bram Lillard and consisted of Dr. Matthew R. Avery, Dr. Juan D. Remolina Gonzalez, and Dr. Thomas H. Johnson from the Operational Evaluation Division.

Introduction to Git

Dr. John T. Haman, Project Leader

Dr. Curtis G. Miller

Executive Summary

Version control software manages, archives, and (optionally) distributes different versions of files. Git is the most popular program for version control and serves as the backbone for websites such as Github, Bitbucket, and others.

In this mini-tutorial we will introduce basics of version control in general, and Git in particular. We focus on two aspects of version control: maintaining a history of a project, and maintaining multiple simultaneous versions. Effective history management keeps a project clean and means that previous versions can be stored should they prove useful while formalizing the history-management process. Maintaining simultaneous file versions facilitates collaboration and the creation of similar products.

Participants will be able to get started using Git right away. The tutorial covers the basics, including creating a repository, storing it externally on GitHub, tracking changes via commits, sharing those changes, getting others' changes, recovering old versions of a project, branching a project into multiple (simultaneous) versions, and merging versions together.

We show how to use Git from the command line and also how online tools provided by GitHub can help with the process and understanding a repository's features. We also describe some Git and reproducible research best practices and demonstrate them through a notional project.

We also explain what role Git plays in a reproducible research context. Git itself will not make research reproducible, but by systematically tracking the history of a project, Git shows the relationship between chosen analytical methods, data used, and the results and conclusions. All of these factors often change as a project evolves over time, and Git tracks that evolution.

Introduction

We will see basic Git usage and concepts

- Getting Started
- Repos
- Tracking Data
- Branches
- Conclusion

Git is a popular and powerful open-source, version control software system

- Version control software manages changes in files as files are edited over time and by different users
- With Git, users can track changes made to files and back up old versions of files
- When multiple variants of a product need to be managed or different people make changes, Git tracks the differences across branches

git

Getting Started

Git is free, open source, and the de facto version control system

git --distributed-is-the-new-centralized

Git is a **free and open source** distributed version control system designed to handle everything from small to very large projects with speed and efficiency.

Git is **easy to learn** and has a **tiny footprint with lightning fast performance**. It outclasses SCM tools like Subversion, CVS, Perforce, and ClearCase with features like **cheap local branching**, convenient **staging areas**, and **multiple workflows**.

- Visit <http://git-scm.com/> to download a copy of Git for your operating system (or use your operating system's package manager, if available)
- Follow the instructions of the installer to get set up
- We will be working in a Windows environment for this tutorial

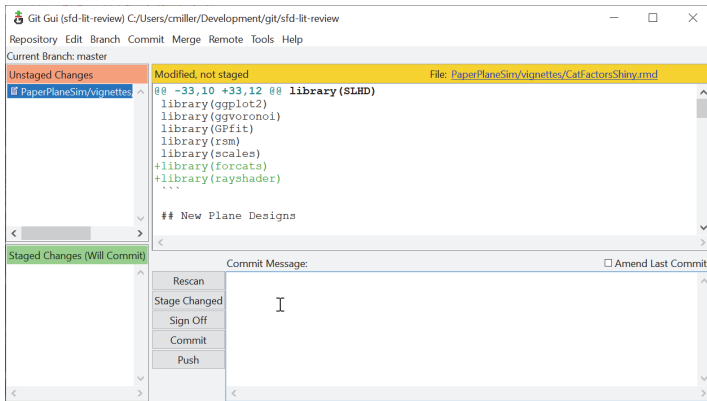

I'm going to assume you have Git installed now.

You can open a Bash terminal to issue Git commands via a right-click on a directory on Windows

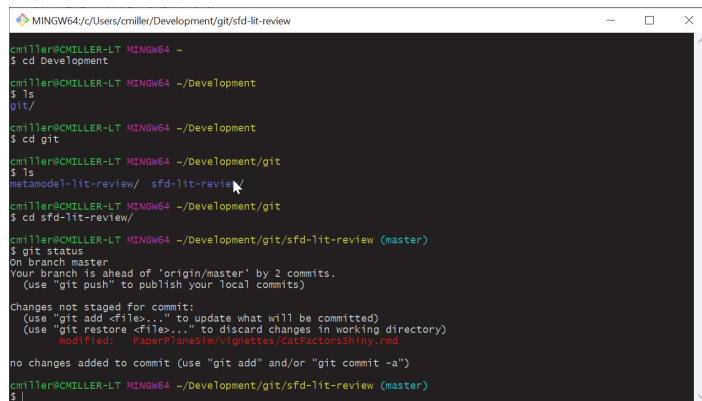

On Windows: click the folder, then right-click for this menu, then click Git Bash for a Bash terminal, or Git GUI for a graphical interface

Git on Windows provides a GUI and a Bash command line

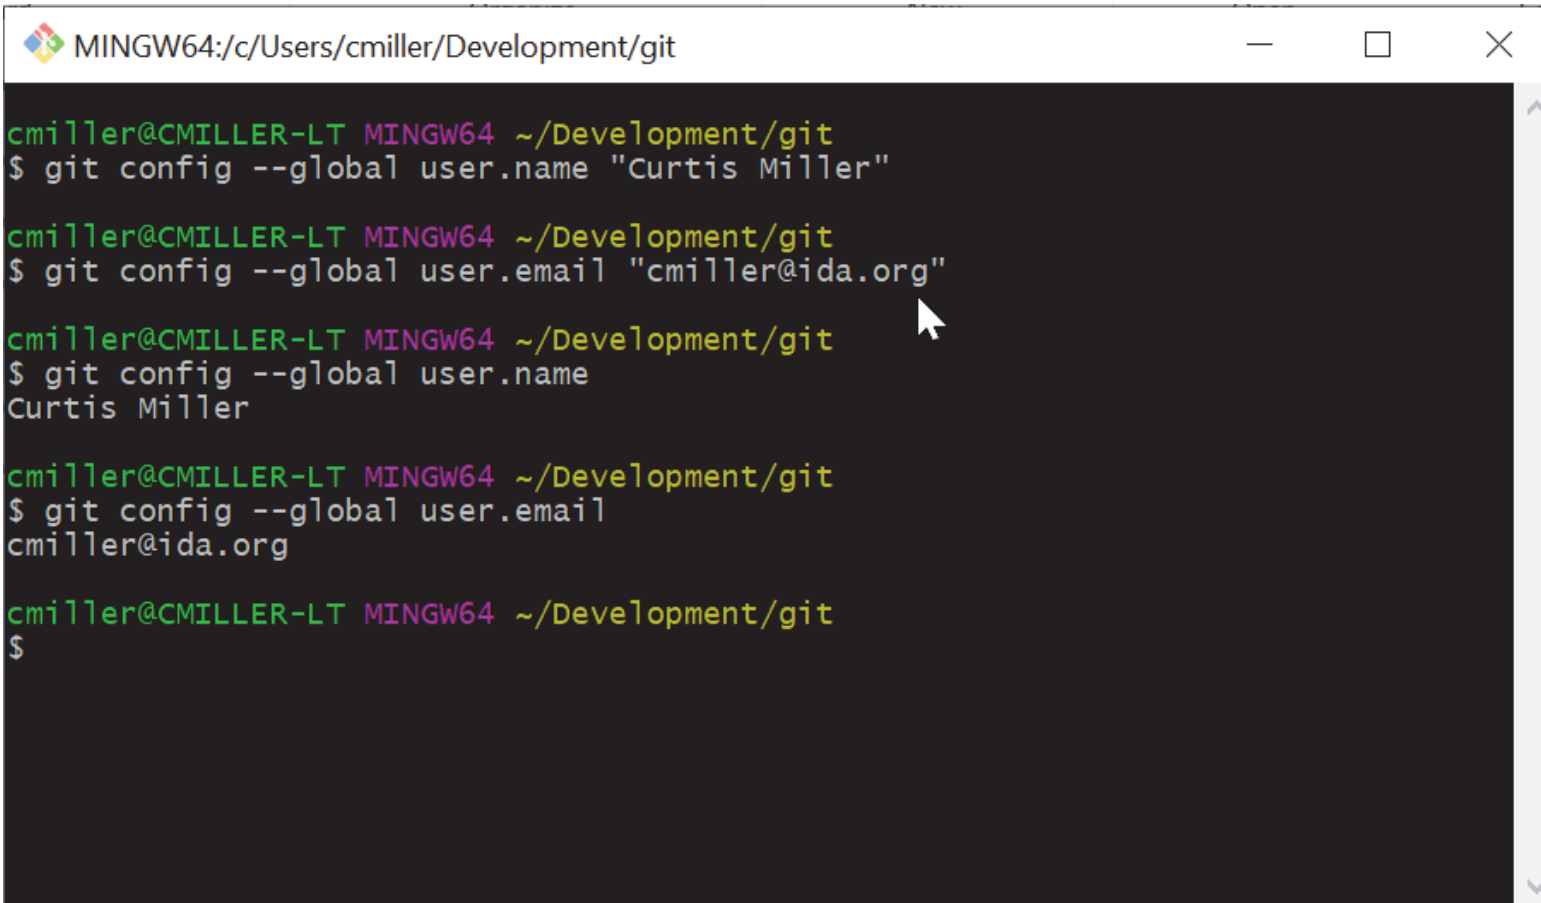

- The Windows Git installer provides both a GUI and a Bash terminal emulator for using Git
- While the GUI may seem beginner friendly, it serves mostly as a front-end to the command line interface
- Full utilization of Git's power is easiest when using the command line
- Git concepts are easier to explain when using the command line

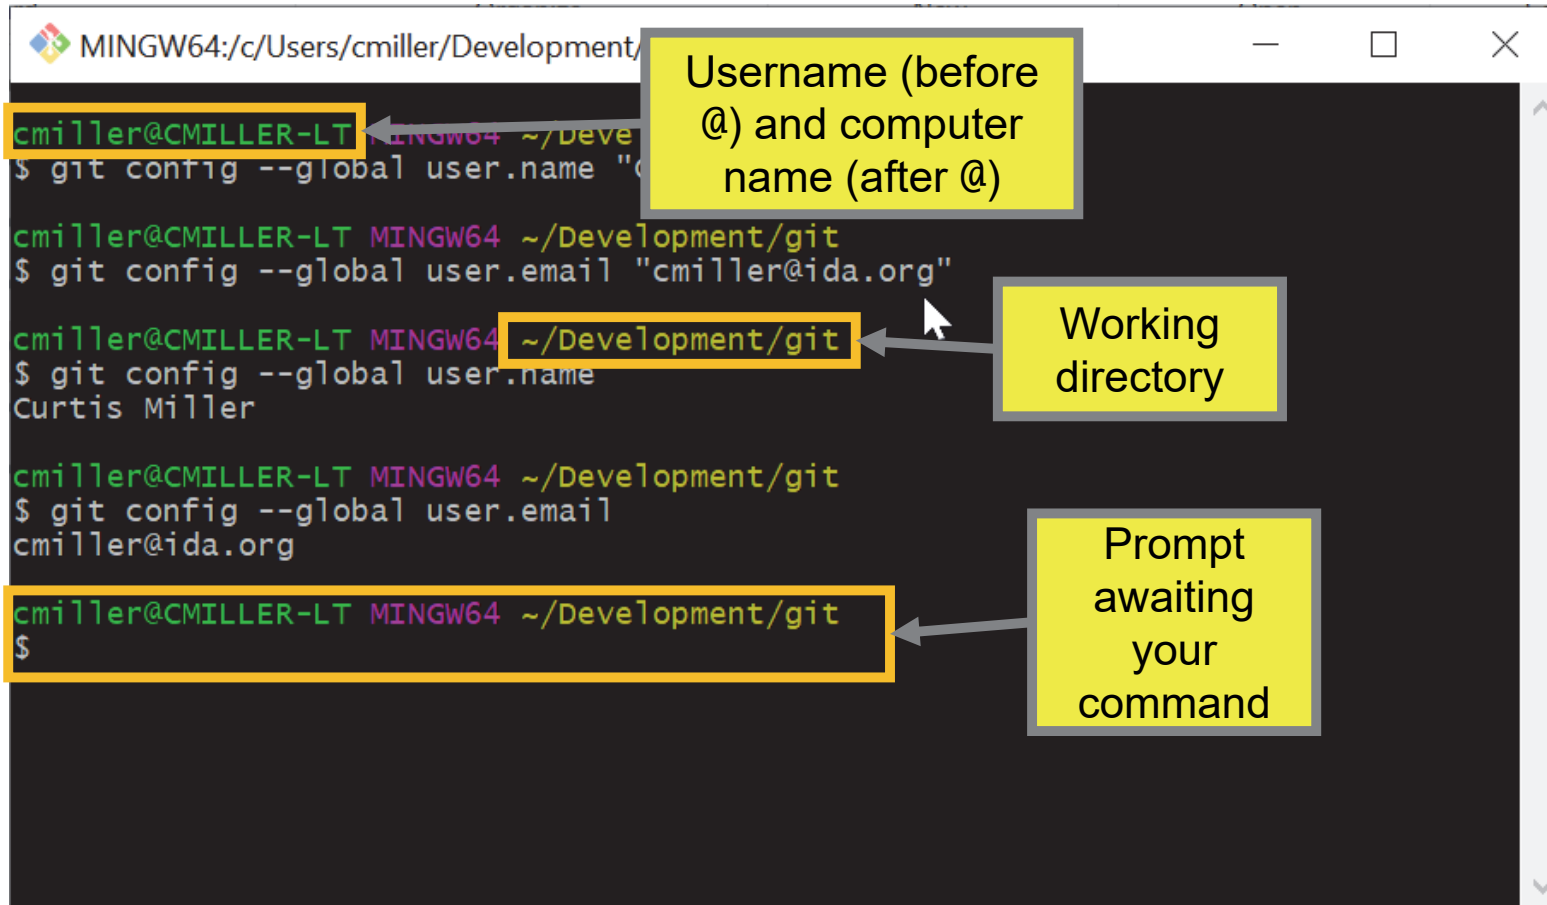

GUI: Graphical User Interface

Set up initial user parameters using git-config

```
MINGW64:/c/Users/cmiller/Development/git  
cmiller@CMILLER-LT MINGW64 ~/Development/git  
$ git config --global user.name "Curtis Miller"  
cmiller@CMILLER-LT MINGW64 ~/Development/git  
$ git config --global user.email "cmiller@ida.org"  
cmiller@CMILLER-LT MINGW64 ~/Development/git  
$ git config --global user.name  
Curtis Miller  
cmiller@CMILLER-LT MINGW64 ~/Development/git  
$ git config --global user.email  
cmiller@ida.org  
cmiller@CMILLER-LT MINGW64 ~/Development/git  
$
```

We can determine a lot from a Bash prompt

A terminal window titled "MINGW64:/c/Users/cmiller/Development/" showing a series of Git configuration commands and their outputs. The prompts are annotated with yellow boxes and arrows pointing to explanatory text:

- Username (before @) and computer name (after @):** Points to the prompt `cmiller@CMILLER-LT`.
- Working directory:** Points to the prompt `~/Development/git`.
- Prompt awaiting your command:** Points to the prompt `$`.

```
MINGW64:/c/Users/cmiller/Development/
cmiller@CMILLER-LT MINGW64 ~/Development
$ git config --global user.name "cmiller"
cmiller@CMILLER-LT MINGW64 ~/Development/git
$ git config --global user.email "cmiller@ida.org"
cmiller@CMILLER-LT MINGW64 ~/Development/git
$ git config --global user.name Curtis Miller
cmiller@CMILLER-LT MINGW64 ~/Development/git
$ git config --global user.email cmiller@ida.org
cmiller@CMILLER-LT MINGW64 ~/Development/git
$
```

Bash is *not* Git; it is a shell (like PowerShell on Windows) and the default shell of Linux. We are talking about Git today, not Bash, though you may learn a little about Bash in the process.

We are using Git via Bash.

We can configure Git to know who we are; this information will be useful when others look at the Git history and see your work

```
MINGW64:/c/Users/cmiller/Development/git
cmiller@CMTLLER-LT MINGW64 ~/Development/git
$ git config --global user.name "Curtis Miller"
cmiller@CMTLLER-LT MINGW64 ~/Development/git
$ git config --global user.email "cmiller@ida.org"
cmiller@CMTLLER-LT MINGW64 ~/Development/git

Curtis Miller
cmiller@CMTLLER-LT MINGW64 ~/Development/git
$ git config --global user.email
cmiller@ida.org
cmiller@CMTLLER-LT MINGW64 ~/Development/git
$
```

Tell Git what my name is. I need to put my name in quotes to make sure that the space character is a part of the name.

Similarly, tell Git my e-mail address

If we don't supply a name/e-mail, this command reports the current settings

“How interesting! How can I learn more about how this command works?”

DESCRIPTION

Git powers popular code sharing websites such as GitHub

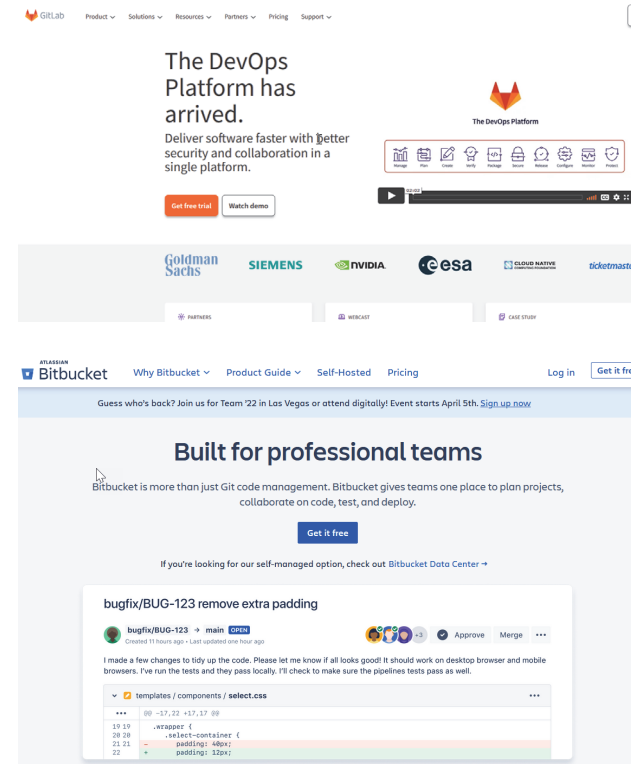

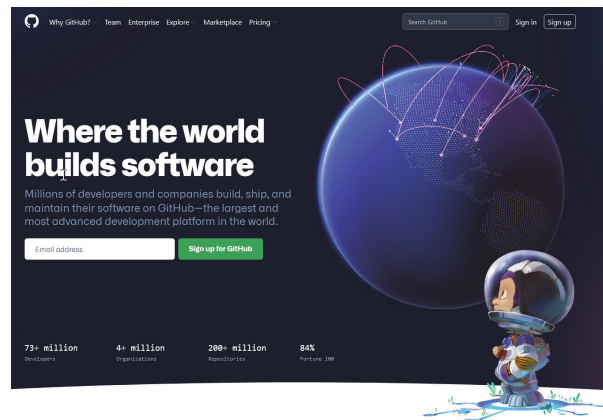

Repos

A Git repository is a collection of tracked files

- Git tracks the history of these files and their differences across time and between branches
- Repos generally contain entire projects
- Users access the project by accessing the repo, and the project is shared by sharing the repo
- Repos are as simple as folders containing files

Many web services host repos (but you don't need to use these to use Git on your own computer)

We can create a repo on GitHub and then clone it to a personal computer

The browser's address bar shows the URL 'https://github.com/ntguardian/DATAWorks22-Git-Intro'. The page header includes navigation links for 'Pulls', 'Issues', 'Marketplace', and 'Explore'. The repository name 'ntguardian / DATAWorks22-Git-Intro' is displayed as 'Public'. Below the repository name, there are buttons for 'Pin', 'Unwatch' (1), 'Fork' (0), and 'Star' (0). A navigation bar contains links for 'Code', 'Issues', 'Pull requests', 'Actions', 'Projects', 'Wiki', 'Security', and 'Insights'. The main content area shows the 'main' branch selected, with buttons for 'Go to file', 'Add file', and 'Code'. A commit history table is visible, showing an initial commit by 'ntguardian' with files '.gitignore' and 'LICENSE'. A blue box prompts the user to 'Add a README'. On the right side, the 'About' section states 'This is a repository for demonstrating how to use Git.' and shows '0 stars', '1 watching', and '0 forks'. Below this, the 'Releases' section indicates 'No releases published' with a link to 'Create a new release'. The 'Packages' section indicates 'No packages published' with a link to 'Publish your first package'. A mouse cursor is visible near the bottom center of the page.

Tracking Data

Git tracks changes via commits

- A Git commit is the basic unit by which Git tracks changes to tracked files
- The Git user adds files for Git to track and tells Git when to track changes made to a file
- For text files, Git tracks only the difference between the current file and the most recent version
- Users can “check out” previous commits to recover the (tracked) state of the project at the time of the commit

Using Git is like belaying* while mountain climbing; if you fall, you fall three feet, not three hundred feet

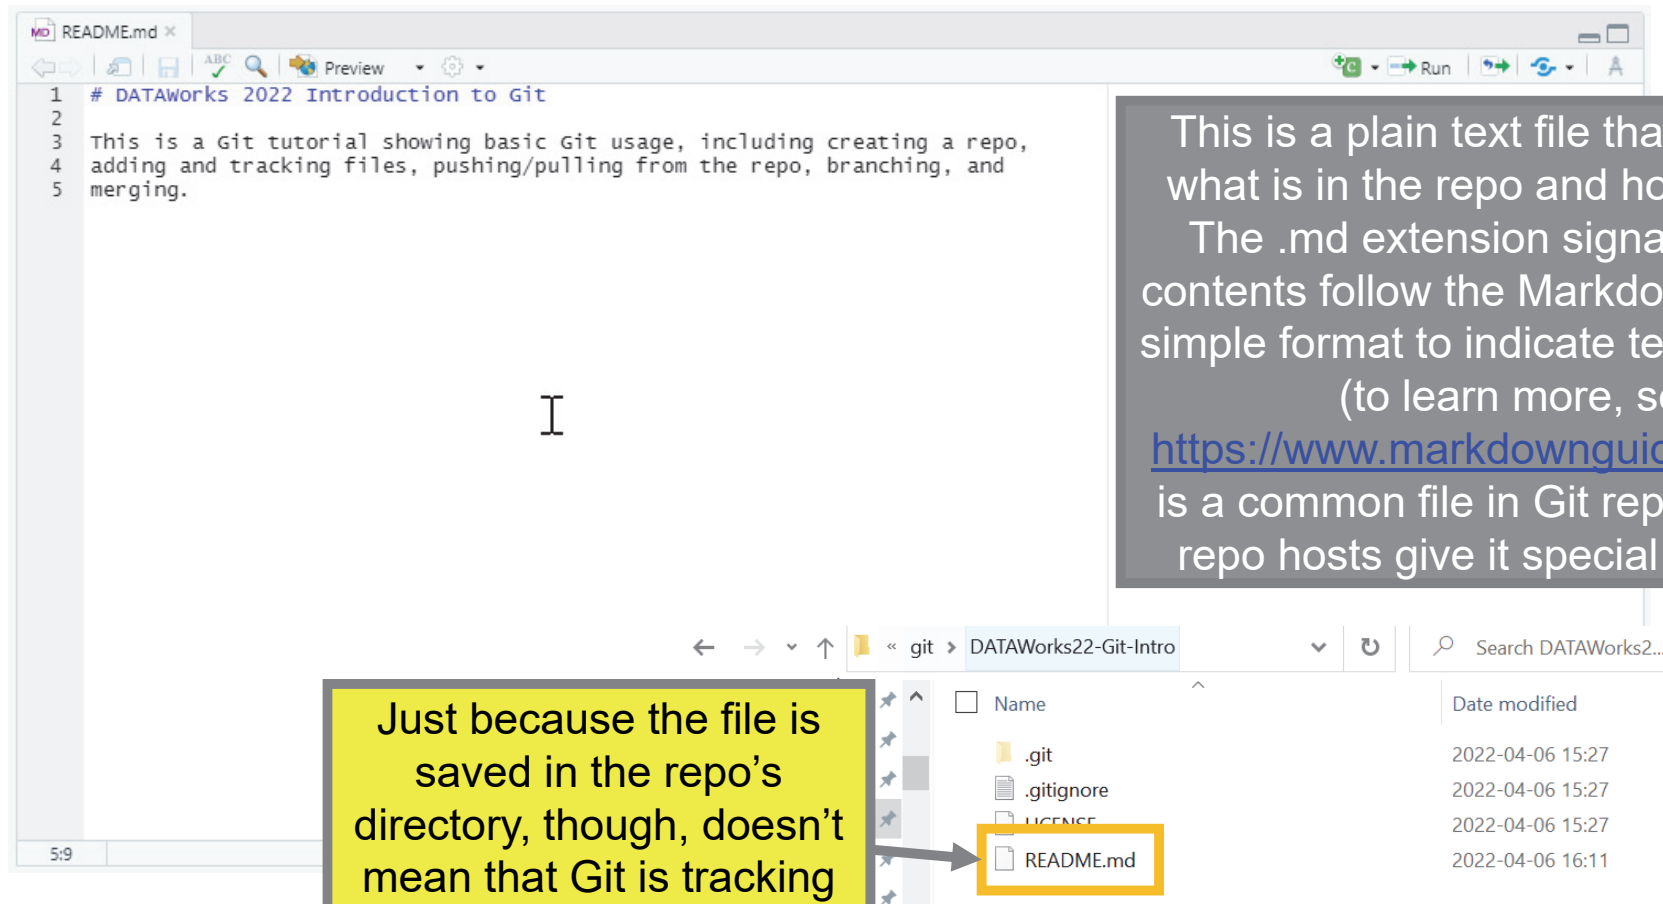

- With Git, you can track changes as they are made
- If you make an immediate mistake, it can be undone
- If you made a mistake several weeks ago that is not obvious until now, Git can help find where the error happened and help address it
- If a deleted file turns out to be useful, you can retrieve it
- You can branch to try out an idea without losing the original files known to work
- You can easily manage multiple versions of a product simultaneously

Wikimedia Commons

*Belaying is climbing a rock wall with a rope. The climber is attached to a rope that is either held by someone at the top of the cliff or looped around something sturdy while a partner stands on the ground with the other end of the rope. As the climber progresses, their partner keeps the rope taut; should the climber let go of the wall, they will only fall as far as the slack in the rope allows, which keeps the climber safe and ensures not too much progress is lost.

Our Git repo should have a README.md file; let's make one!

The screenshot shows a code editor window with a file named 'README.md'. The content of the file is as follows:

```
1 # DATAWorks 2022 Introduction to Git
2
3 This is a Git tutorial showing basic Git usage, including creating a repo,
4 adding and tracking files, pushing/pulling from the repo, branching, and
5 merging.
```

Below the editor, a file explorer shows the directory structure of the repository. The files listed are:

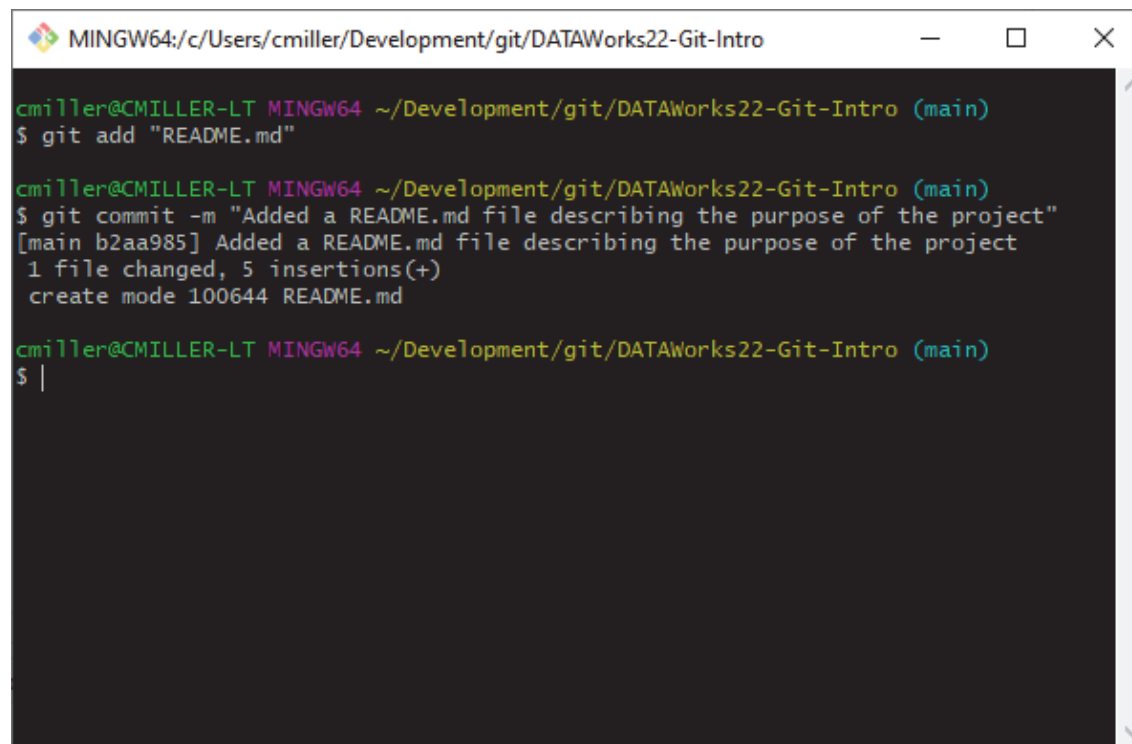

Name	Date modified
.git	2022-04-06 15:27
.gitignore	2022-04-06 15:27
LICENSE	2022-04-06 15:27
README.md	2022-04-06 16:11

The 'README.md' file is highlighted with a yellow box in the file explorer.

This is a plain text file that describes what is in the repo and how to use it. The .md extension signals that the contents follow the Markdown format, a simple format to indicate text formatting (to learn more, see <https://www.markdownguide.org>). This is a common file in Git repos so some repo hosts give it special treatment.

Just because the file is saved in the repo's directory, though, doesn't mean that Git is tracking it; we need to make a commit that adds it.

Use `git commit` to create a commit that adds the file and describes its contents

```
MINGW64:/c/Users/cmiller/Development/git/DATAWorks22-Git-Intro
cmiller@CMILLER-LT MINGW64 ~/Development/git/DATAWorks22-Git-Intro (main)
$ git add "README.md"

cmiller@CMILLER-LT MINGW64 ~/Development/git/DATAWorks22-Git-Intro (main)
$ git commit -m "Added a README.md file describing the purpose of the project"
[main b2aa985] Added a README.md file describing the purpose of the project
1 file changed, 5 insertions(+)
 create mode 100644 README.md

cmiller@CMILLER-LT MINGW64 ~/Development/git/DATAWorks22-Git-Intro (main)
$ |
```

Use `git commit` to create a commit that adds the file and describes its contents

Name the file with the changes to track

`git add` is the command for adding changes to a commit to track

`git commit` is the command for creating a commit, a “save point” containing a set of changes made to the files in a repo

The `-m` option is for adding a message summarizing what changes were made in the commit (keep it short)

```
MINGW64~/Development/git/DATAWorks22-Git-Intro
cmliller@CMTILLER-LT MINGW64 ~/Development/git/DATAWorks22-Git-Intro (main)
$ git add "README.md"
cmliller@CMTILLER-LT MINGW64 ~/Development/git/DATAWorks22-Git-Intro (main)
$ git commit -m "Added a README.md file describing the purpose of the project"
[main b2aa98] Added a README.md file describing the purpose of the project
1 file changed, 5 insertions(+)
create mode 100644 README.md
cmliller@CMTILLER-LT MINGW64 ~/Development/git/DATAWorks22-Git-Intro (main)
```

Our local git repo now has this commit, but the remote repo (on GitHub) is unaware of it and is unchanged.

Use git push/git pull to keep your local repo copy up-to-date

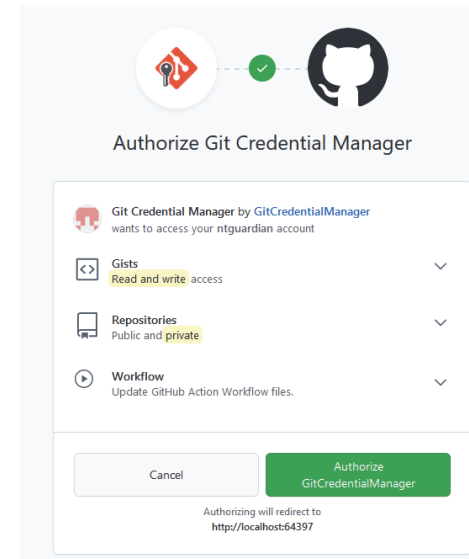

- The commands `git push` and `git pull` keep local copies of git repositories up-to-date with the external host of the repository
- After committing changes, use `git push` to propagate those changes to the host (and thus to everyone else with an up-to-date repo)
- Push changes at least at the end of the day when work is done
- Use `git pull` to make the local repo up-to-date with whatever is on the server
- Pull changes at the start of the day before starting work

Pushing to GitHub for the first time may require authentication

```
MINGW64:/c/Users/cmiller/Development/git/DATAWorks22-Git-Intro  
cmiller@CMILLER-LT MINGW64 ~/Development/git/DATAWorks22-Git-Intro (main)

12 ## Problem 9
13
14 *This question is about creating models for calibration of satellite remote
15 sensed data. The data frame `chl` contains direct ship based measurements of
16 chlorophyll concentrations in the top 5 metres of ocean water, `chl`, as well as
17 the corresponding satellite estimate `chl.sw` (actually a multi-year average
18 measurement for the location and time of year), along with ocean depth, `bath`,
19 day of year, `jul.day` and location, `lon`, `lat`. The data are from the world
20 ocean database (see http://seawifs.gsfc.nasa.gov/SEAWIFS/ for information on
21 Seawifs). `chl` and `chl.sw` do not correlate all that well with each other,
22 probably because the reflective characteristics of water tend to change with
23 time of year and whether the water is near the coast (and hence full of
24 particulate matter) or open ocean. One way of improving the predictive power of
25 the satellite observations might be to model the relationship between directly
26 measured chlorophyll and remote sensed chlorophyll, viewing the relationship as
27 an indicator for water type (near shore vs. open), a model something like*
28
29 
$$f_1(\text{chl}_i) = f_1(\text{chl.sw}_i) f_2(\text{bath}_i)$$

30 
$$f_3(\text{jul.day}_i)$$

31
32 *might be a reasonable starting point.*

We're structuring the project around a statistical analysis of ocean chlorophyll data using generalized additive models. That will be described in a file stored in the vignettes directory. README.md has been changed to reflect this purpose.

Repeating these three commands will be 90% of your Git commands

Instead of listing files to track individually, use this option to add all changes made to any file in the repo (unless that file is ignored; more on that later)

Push your commands to the remote host; you don't need to do this with every commit, but do it at least at the end of a workday, or when wanting to share immediately

You control when you commit. Don't commit a bunch of little changes, but don't make several big changes and commit all at once. Find a middle ground. You should probably commit changes multiple times a day (don't worry about saving space too much)

To demonstrate this project, I will work an exercise from Simon Wood's book, *Generalized additive models; An introduction with R (2nd ed.)*. The exercise concerns using generalized additive models (GAMs) for calibrating satellite remote sensed data via comparing remote sensed chlorophyll in the ocean via satellite with direct chlorophyll measurement. DATAWorks 2022 Introduction to Git

This is a Git tutorial showing basic Git usage, including creating a repo, adding and tracking files, pushing/pulling from the repo, branching, and merging.

We can also see what a repo looked like at the moment a commit was made

The screenshot shows a GitHub repository interface. At the top, the repository name is 'b2aa985f4b'. Below it, there's a 'Switch branches/tags' dropdown menu with 'main' selected and 'default' as an option. A yellow callout box with the text 'Click to go back to the current state' points to the 'main' branch and the commit hash 'b2aa985f4b'. The commit history shows two commits: 'Initial commit' and 'Added a README.md file describing the purpose of the project', both dated 'yesterday'. Below the commit history, the README file content is visible, titled 'DATAWorks 2022 Introduction to Git', with the text: 'This is a Git tutorial showing basic Git usage, including creating a repo, adding and tracking files, pushing/pulling from the repo, branching, and merging.'

We can do this without GitHub using `git checkout`

```
MINGW64:/c/Users/cmiller/Development/git/DATAWorks22-Git-Intro
cmiller@CMILLER-LT MINGW64 ~/Development/git/DATAWorks22-Git-Intro (main)
$ git checkout b2aa985
Note: switching to 'b2aa985'.

You are in 'detached HEAD' state. You can look around, make experimental
changes and commit them, and you can discard any commits you make in this
state without impacting any branches by switching back to a branch.

If you want to create a new branch to retain commits you create, you may
do so (now or later) by using -c with the switch command. Example:

    git switch -c <new-branch-name>

Or undo this operation with:

    git switch -

Turn off this advice by setting config variable advice.detachedHead to false

HEAD is now at b2aa985 Added a README.md file describing the purpose of the project
cmiller@CMILLER-LT MINGW64 ~/Development/git/DATAWorks22-Git-Intro ((b2aa985...))
```

This will bring a repo's files to a previously tracked state

git checkout gets different versions of the repo, including old commits and branches

```

1 # DATAWorks 2022 Introduction to Git
2
3 This is a Git tutorial showing basic Git usage, including creating a repo,
4 adding and tracking files, pushing/pulling from the repo, branching, and
5 merging.

Just say what file you want

The image shows a terminal window and a file editor. The terminal window is titled "MINGW64:/c:/Users/cmiller/Development/git/DATAWorks22-Git-Intro". It shows the following commands and output:

```
cmiller@CMILLER-LT MINGW64 ~/Development/
$ git checkout b2aa985 README.md
Updated 1 path from df8095b

cmiller@CMILLER-LT MINGW64 ~/Development/
$ git reset --hard
HEAD is now at 0f66f94 Structuring project analysis example

cmiller@CMILLER-LT MINGW64 ~/Development/git/DATAWorks22-Git-Intro (main)
$
```

Two yellow callout boxes with arrows point to the file names in the terminal: "Name the file you want" points to "README.md" and "Up next..." points to "README.md".

The file editor window shows the content of "README.md":

By the way, I had a hard time pushing changes to GitHub because, as of August 14, 2021, GitHub won't accept passwords on the command line. I had to generate a token and use that as my password. This was a headache that took a long time to deal with. Be warned that this may be an issue when communicating with GitHub.

We can see these changes on GitHub and now need to get them locally

The screenshot shows a GitHub repository interface. At the top, there are navigation elements: a dropdown menu for 'main', '1 branch', and '0 tags'. To the right are buttons for 'Go to file', 'Add file', and 'Code'. Below this is a commit history table with the following entries:

This command downloads all changes and brings the files up-to-date (it will fail if you have local changes)

This is a summary of what's changed and how much

You should run this at least in the morning before starting work to make sure you're up-to-date. Run again if someone just made changes needed immediately.

Now those changes are available to work with

Problem 9

This question is about creating models for calibration of satellite remote sensed data. The data frame chl contains direct ship based measurements of chlorophyll concentrations in the top 5 metres of ocean water, chl, as well as the corresponding satellite estimate chl.sw (actually a multi-year average measurement for the location and time of year), along with ocean depth, bath, day of year, jul.day and location, Lon, Lat. The data are from the world ocean database (see <http://seawifs.gsfc.nasa.gov/SEAWIFS/> for information on SeaWifs). chl and chl.sw do not correlate all that well with each other, probably because the reflective characteristics of water tend to change with time of year and whether the water is near the coast (and hence full of portulacate matter) or open ocean. One way of improving the predictive power of the satellite observations might be to model the relationship between directly measured chlorophyll and remote sensed chlorophyll, viewing the relationship as an indicator for water type (near shore vs. open), a model something like

$$\mathbb{E}(\text{chl}_i) = f_1(\text{chl.sw}_i)f_2(\text{bath}_i)f_3(\text{jul.day}_i)$$

might be a reasonable starting point.

Part (a)

Plot the response data and predictors against each other using pairs. Notice that some predictors have very skewed distributions. It is worth trying some simple power transformations in order to get a more even spread of predictors, and reduce the chance of a few points being overly influential. Find appropriate transformations.

It seems that bath has strange outlier behavior, so we will try to use a power transform for it. Longitude and latitude may also be more useful transformed.

- .gitignore describes files that, by default, should not be tracked in commits
- .gitignore is a plain text file containing descriptions of files that should be ignored
- File names and locations can be entered manually
- Pattern can also be used to describe classes of files to be ignored; if a file name matches the pattern the file will be ignored
- See <https://git-scm.com/docs/gitignore> for more information on writing a .gitignore file

GitHub already made a .gitignore file with defaults

The image shows a code editor window with a file named `.gitignore` open. The file contains several lines of text, each representing a pattern to ignore. Annotations in yellow boxes with arrows point to specific lines, explaining their meaning:

- Line 1: `# History files` (Comment; understood by a reader, ignored by Git)
- Line 2: `.Rhistory`
- Line 3: `.Rapp.history`
- Line 5: `# Session Data files` (Comment; understood by a reader, ignored by Git)
- Line 6: `.RData` (Ignore any file ending in `.Rdata` anywhere in the repo)
- Line 8: `# User-specific files` (Comment; understood by a reader, ignored by Git)
- Line 9: `.Ruserdata`
- Line 11: `# Example code` (Comment; understood by a reader, ignored by Git)
- Line 12: `*-Ex.R` (Ignore file like "Test-Ex.R" or "my_func_Ex.R" anywhere)
- Line 14: `# Output files from R CMD SHLIB` (Comment; understood by a reader, ignored by Git)
- Line 15: `/*.tar.gz` (In the base directory, ignore files ending in `.tar.gz`)
- Line 17: `# Output files from R CMD SHLIB` (Comment; understood by a reader, ignored by Git)
- Line 18: `/*.Rcheck/` (Ignore any directories with `.Rcheck` in their name)
- Line 20: `# Rstudio files` (Comment; understood by a reader, ignored by Git)
- Line 21: `.Rproj.user/` (Ignore all files in this directory)
- Line 23: `# produced vignettes` (Comment; understood by a reader, ignored by Git)
- Line 24: `vignettes/*.html`
- Line 25: `vignettes/*.pdf` (In the vignettes directory, ignore files ending in `.html` or `.pdf`)

The editor window also shows a status bar at the bottom with `1:1` and a dropdown menu labeled `Gitignore`.

Now just add a line to ignore Word (.docx) files

```
23 # produced vignettes

Basic change tracking commands

Command	Description	Examples
<code>git add</code>	Add changes to (or brand new) files to a staged commit	<code>git add myfile.txt</code> <code>git add --all</code>
<code>git commit</code>	Commit changes	<code>git commit -m "Message"</code>
<code>git pull</code>	For repos hosted remotely (such as GitHub), update repo with changes from host	<code>git pull</code>
<code>git push</code>	For repos hosted remotely (such as GitHub), send changes to host	<code>git push</code>
<code>git rm</code>	Remove a file from tracking	<code>git rm myfile.txt</code>
<code>git reset</code>	Git's "undo" command	<code>git reset --hard</code> # CAUTION: Deletes changes
<code>git diff</code>	Compare commits and branches	<code>git diff HEAD~ HEAD</code> <code>git diff HEAD~ HEAD myfile.txt</code> <code>git diff onebranch otherbranch</code>
<code>git status</code>	Show the status of a repo (such as what will be changed in a commit)	<code>git status</code>
<code>git log</code>	See commit history	<code>git log</code>
<code>git checkout</code>	Retrieve data from commits	<code>git checkout identifier</code>

Branches

Branches allow multiple versions of files to exist and be tracked simultaneously

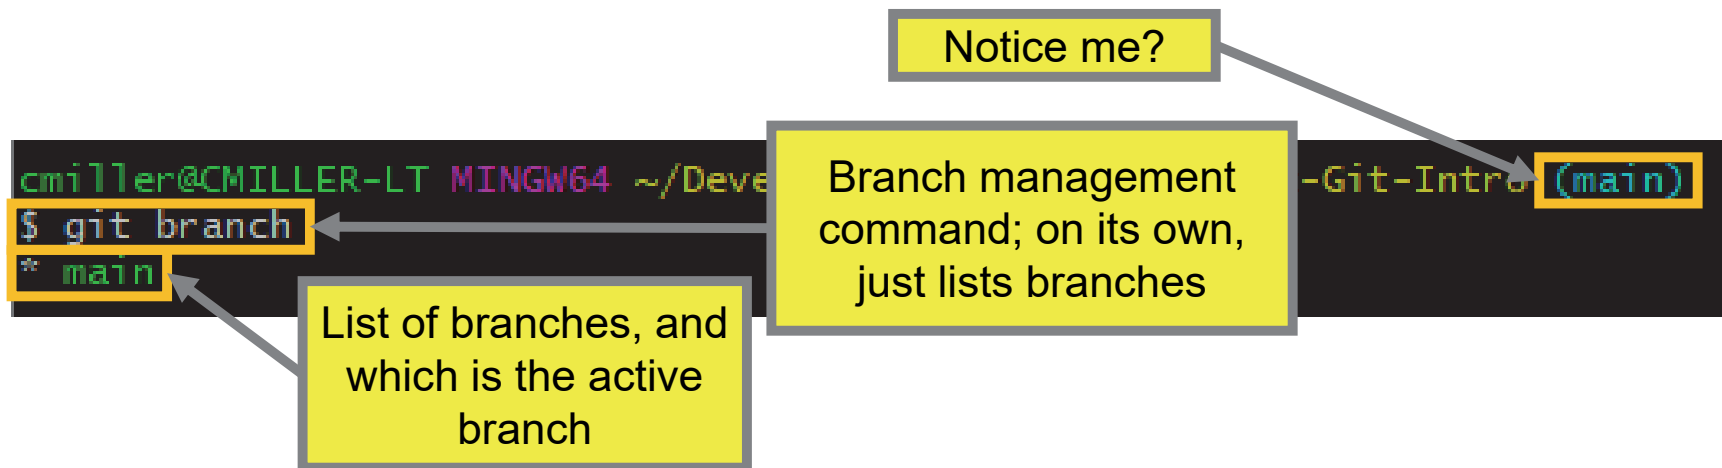

- Commits represent moving forward and backward in time while branches allow for differences between files to exist simultaneously
- Git can track the difference between branches and propagate a change that affects both branches while maintaining what makes them distinct
- Changes made in one branch can be merged into another branch
- Branching provides a means for collaboration; each collaborator creates their own private branch to do their work
- Branching allows collaborators to simultaneously maintain different versions of a product

What branches do we start out with?

```
cmiller@CMILLER-LT MINGW64 ~/Development/git/DATAWorks22-Git-Intro (main)
$ git branch
* main
```

The branch that best represents the project's most stable state is the main branch

Let's create a personal branch

With the `-b` option, creates a new branch with the branch name following

```
cmiller@CMILLER-LT MINGW64 ~/Development/git/DATAWorks22-Git-Intro (main)
$ git checkout -b cmiller
Switched to a new branch 'cmiller'

cmiller@CMILLER-LT MINGW64 ~/Development/git/DATAWorks22-Git-Intro (cmiller)
$ git branch
* cmiller
  main
```

Notice me?

List of branches; cmiller is the active branch

When using Git with a team, avoid editing the main branch directly. Make edits on a personal branch freely. Changes to the main branch should be done via merging changes from other branches most of the time (we will discuss branch merging later). Only when the team is ready to “accept” edits should the main branch be changed.

Now work primarily with the personal branch

78 Let's consider the range of the response variable:
79
80 ```{r}
81 range(ch1_transform$ch1)
82
83
84 The gamma distribution makes for an attractive potential distribution family,
85 due to being non-negative, but unfortunately there are concentrations of zero. A
86 quick fix would be to add a small value to the zeroes, reflecting the fact that
87 such a concentration likely is an issue with rounding.
88
89 ```{r}
90 ch1_transform <- mutate(ch1_transform, ch1 = ifelse(ch1 == 0, 0.001, ch1))
91
92
93 Now fit a GAM.
94
95 ```{r}
96 ch1_fit <- gam(ch1 ~
97   s(tr.lon, k = 60, bs = 'cr') +
98   s(tr.lat, k = 60, bs = 'cr') +
99   s(tr.bath, k = 60, bs = 'cr') +
100   s(jul.day, k = 120, bs = 'cr') +
101   s(ch1.sw, k = 60, bs = 'cr'),
102   data = ch1_transform,
103   family = Gamma(link = "log"),
104   method = "REML"
105 )
106
107
108 Sadly the latitude and longitude are not interacted due to time to compute
109 solution being too long.
110
111 ### Part (c)
112
113 *In this sort of modeling the aim is to improve on simply using the satellite
114 measurements as predictions of the direct measurements. Given the large number
115 of data, it is easy to end up using rather complex models after quite a lot of
116 examination of the data. It is therefore important to check that the model is

Use git merge to propagate changes made in one branch to another branch

- Eventually one may want to merge the changes made in one branch to another branch
- **git merge** will determine how the two branches should be merged together
- When using Git merge, *check out the destination branch for the merge first*, then call **git merge sourcebranch**
- The changes from the source branch will then be propagated to the destination branch
- Git may ask for a message to be written to explain the merge

A merge may be simple...

```
cmiller@CMILLER-LT MINGW64 ~/Development/git/DATAWorks22-Git-Intro (cmiller)
$ git checkout main
Switched to branch 'main'
Your branch is up to date with 'origin/main'.

cmiller@CMILLER-LT MINGW64 ~/Development/git/DATAWorks22-Git-Intro (main)
$ git merge cmiller

In this case, it was not too hard

```
cmiller@CMILLER-LT MINGW64 ~/Development/git/DATAworks22-Git-Intro (cmiller)

Check out the branch you want to merge into

On this branch, merge in the other branch; now all cmiller branch changes are a part of main

A merger is treated like a new commit

The screenshot shows a GitHub repository page for 'DATAWorks 2022 Introduction to Git'. The commit history table is as follows:

| File | Commit Message | Time |
|------------|--|---------------|
| vignettes | Attempting part (c) but did not complete deviance computation on test... | 8 minutes ago |
| .gitignore | Added knit support for Word files (generated files should be ignored) | yesterday |
| LICENSE | Initial commit | 6 days ago |
| README.md | Structuring project around chlorophyll analysis example | 6 days ago |

Below the commit history, the README.md file is open, showing the title 'DATAWorks 2022 Introduction to Git' and introductory text. A 'Switch branches/tags' dropdown menu is open, displaying a search bar 'Find or create a branch...' and a list of branches: 'main' (marked as default), 'cmiller', and 'probs6n8'. A 'View all branches' link is also visible.

Our log shows a more interesting structure now

```

```

- Two users might edit the same line in two branches in different ways
- When those branches are merged, Git will throw an error and insert lines into files with unresolved differences
- After manually handling the conflicts with a text editor, commit the changes, then carry on; Git will view the conflicts as resolved

Let's introduce a potential merge conflict when we merge into our collaborator's branch...

167 *Using `mgcv::gam`, try modelling the data using a model of the sort suggested

170 dimensions used for smoothing, somewhat (especially for `jul.day`). Use the
171 `"cr"` basis to avoid excessive computational cost.*

Surprised that this is the *only* spot where a merge conflict happens? Git recognizes the differences elsewhere as intended. This allows for making changes to one master version of the project and propagating them to other deviations of the project.

Basic branch management commands

| Command | Description | Examples |
|---------------------------|--|---|
| <code>git branch</code> | Branch management command | <code>git branch -d somebranch</code> # Delete branch
<code>git branch -m old new</code> # Rename branch |
| <code>git checkout</code> | Retrieve data from commits; discussed more later | <code>git checkout identifier</code> |
| <code>git merge</code> | Merge one branch into another branch | <code>git merge branchname</code> |

Conclusion

Git can be an important part of making research reproducible

- As a research project carries on, the data and analysis techniques used are prone to change over time
- Results ultimately depend on the version of data and analysis used at any given time
- With Git, the evolution of the data and the analysis methods is tracked over time
- This allows for someone to see how the results of the project depend on the version of data and analysis used, and track down the specific version of these that made a particular analysis and what changed to produce a more current analysis

This is only the start of learning Git

- Git is powerful and frankly intimidating software
- It is not the most simple version control system out there, but it's popular for good reasons
- I often default to using Git for almost any project, regardless of whether I plan to share or not, or how big the project might be
- The more you use Git, the more familiar it will become
- Remember: `--help`, Google, and StackExchange are your friends

Commands I would love to talk about if I had time

| Command | Description |
|-------------------------|--|
| <code>git log</code> | See commit history; setting options can allow for making useful displays |
| <code>git diff</code> | See what files changed between commits and in what ways |
| <code>git bisect</code> | Find the first "bad" commit (say where a bug was introduced) |
| <code>git stash</code> | "Stash" changes, then reset to the most recent commit |
| <code>git grep</code> | Search an entire repo using regular expressions |

Cheat Sheet for Git

| Command | Description | Examples |
|---------------------------|--|---|
| <code>git config</code> | Configure Git | <code>git config --global user.name "Jane Doe"</code>
<code>git config --global user.email jdoe@ida.org</code> |
| <code>git init</code> | Create a new repo | <code>git init</code> |
| <code>git clone</code> | Clone an existing repository | <code>git clone "https:..."</code> |
| <code>git add</code> | Add changes to (or brand new) files to a staged commit | <code>git add myfile.txt</code>
<code>git add --all</code> |
| <code>git commit</code> | Commit changes | <code>git commit -m "Message"</code> |
| <code>git pull</code> | For repos hosted remotely (such as GitHub), update repo with changes from host | <code>git pull</code> |
| <code>git push</code> | For repos hosted remotely (such as GitHub), send changes to host | <code>git push</code> |
| <code>git rm</code> | Remove a file from tracking | <code>git rm myfile.txt</code> |
| <code>git reset</code> | Git's "undo" command | <code>git reset --hard</code> # CAUTION: Deletes changes |
| <code>git branch</code> | Branch management command | <code>git branch -d somebranch</code> # Delete branch
<code>git branch -m old new</code> # Rename branch |
| <code>git checkout</code> | Retrieve data from commits | <code>git checkout identifier</code> |
| <code>git merge</code> | Merge one branch into another branch | <code>git merge branchname</code> |

BACKUP

Navigating your computer using Bash

| Command | Description | Examples |
|-----------|--|--|
| ls | List information about files or directories | ls # List files
ls -lh # List files with description
ls -lha # List all files with description |
| cd | Change the current working directory | cd "My Documents" # Go to My Documents folder
cd .. # Go to parent directory
cd ~/ # Go to home directory
cd - # Go to last visited |
| pwd | Print the current working directory | pwd |
| head/tail | Show the first few lines/last few lines of a text file (resp.) | head "My file.txt"
tail my_file.txt |
| cat | Can be used to show file contents (but has different purpose) | cat "My file.txt" |
| mv | Move a file; also used to rename files | mv file.txt dir/file.txt
mv oldname.txt newname.txt |
| cp | Copy a file | cp original.txt new.txt |
| mkdir | Create a new directory | mkdir my_new_repo |
| rm | Remove a file | rm filename.txt
rm -r my_new_repo/* # Delete subcontents |
| rmdir | Remove a directory | rmdir my_new_repo |
| exit | Exit the shell | exit |

| 14. ABSTRACT
Version control software manages, archives, and (optionally) different versions of files. Git is the most popular program for version control and serves as the backbone for websites such as Github, Bitbucket, and others. In this mini-tutorial we will introduce basics of version control in general, Git in particular. We explain what role Git plays in a reproducible research context. The goal of the course is to get participants started using Git. We will create and clone repositories, add and track files in a repository, and manage git branches. We also discuss a few Git best practices.

This tutorial was first given at DATAWorks Conference 2022 in Alexandria, Virginia. |
